

Sun PRJNA689204 stool communities, three samples of $\approx$ 125–135 Gb each. a, Bland–Altman summary of sk2bGrow-WGS (B) against Pileup at its shipped defaults (A), on the common denominator of species both methods report ($n = 58/68/78$ per sample): bias is stable at +0.22 to +0.25 $\log_2$ (Pileup reads $\approx$ 16–19% high) with limits of agreement $\approx$ -0.43 to +0.89; the low CCC (0.25–0.37) reflects the narrow observed range (span $\approx$ 1.4 $\log_2$), not broken agreement. Per-species points are not committed; each marker is a sample’s bias with its LoA whisker, annotated with n and the B/A ranges. b, the real-2bRAD arm (C) against the same WGS arm: exact read-level deduplication (95.7% of reads collapse to unique sequences) destroys the PTR signal — Pearson r falls from 0.73–0.80 to 0.30–0.60 and CCC collapses (e.g. S06: r 0.797 to 0.435, CCC 0.728 to 0.192). sk2bGrow’s pipeline must not deduplicate before counting. (raw-arm numbers from the c_arm_diag run, REVIEW §6; deduped from p2_review_agreement.tsv.)
